

HUG SOFTWARE VOLUME

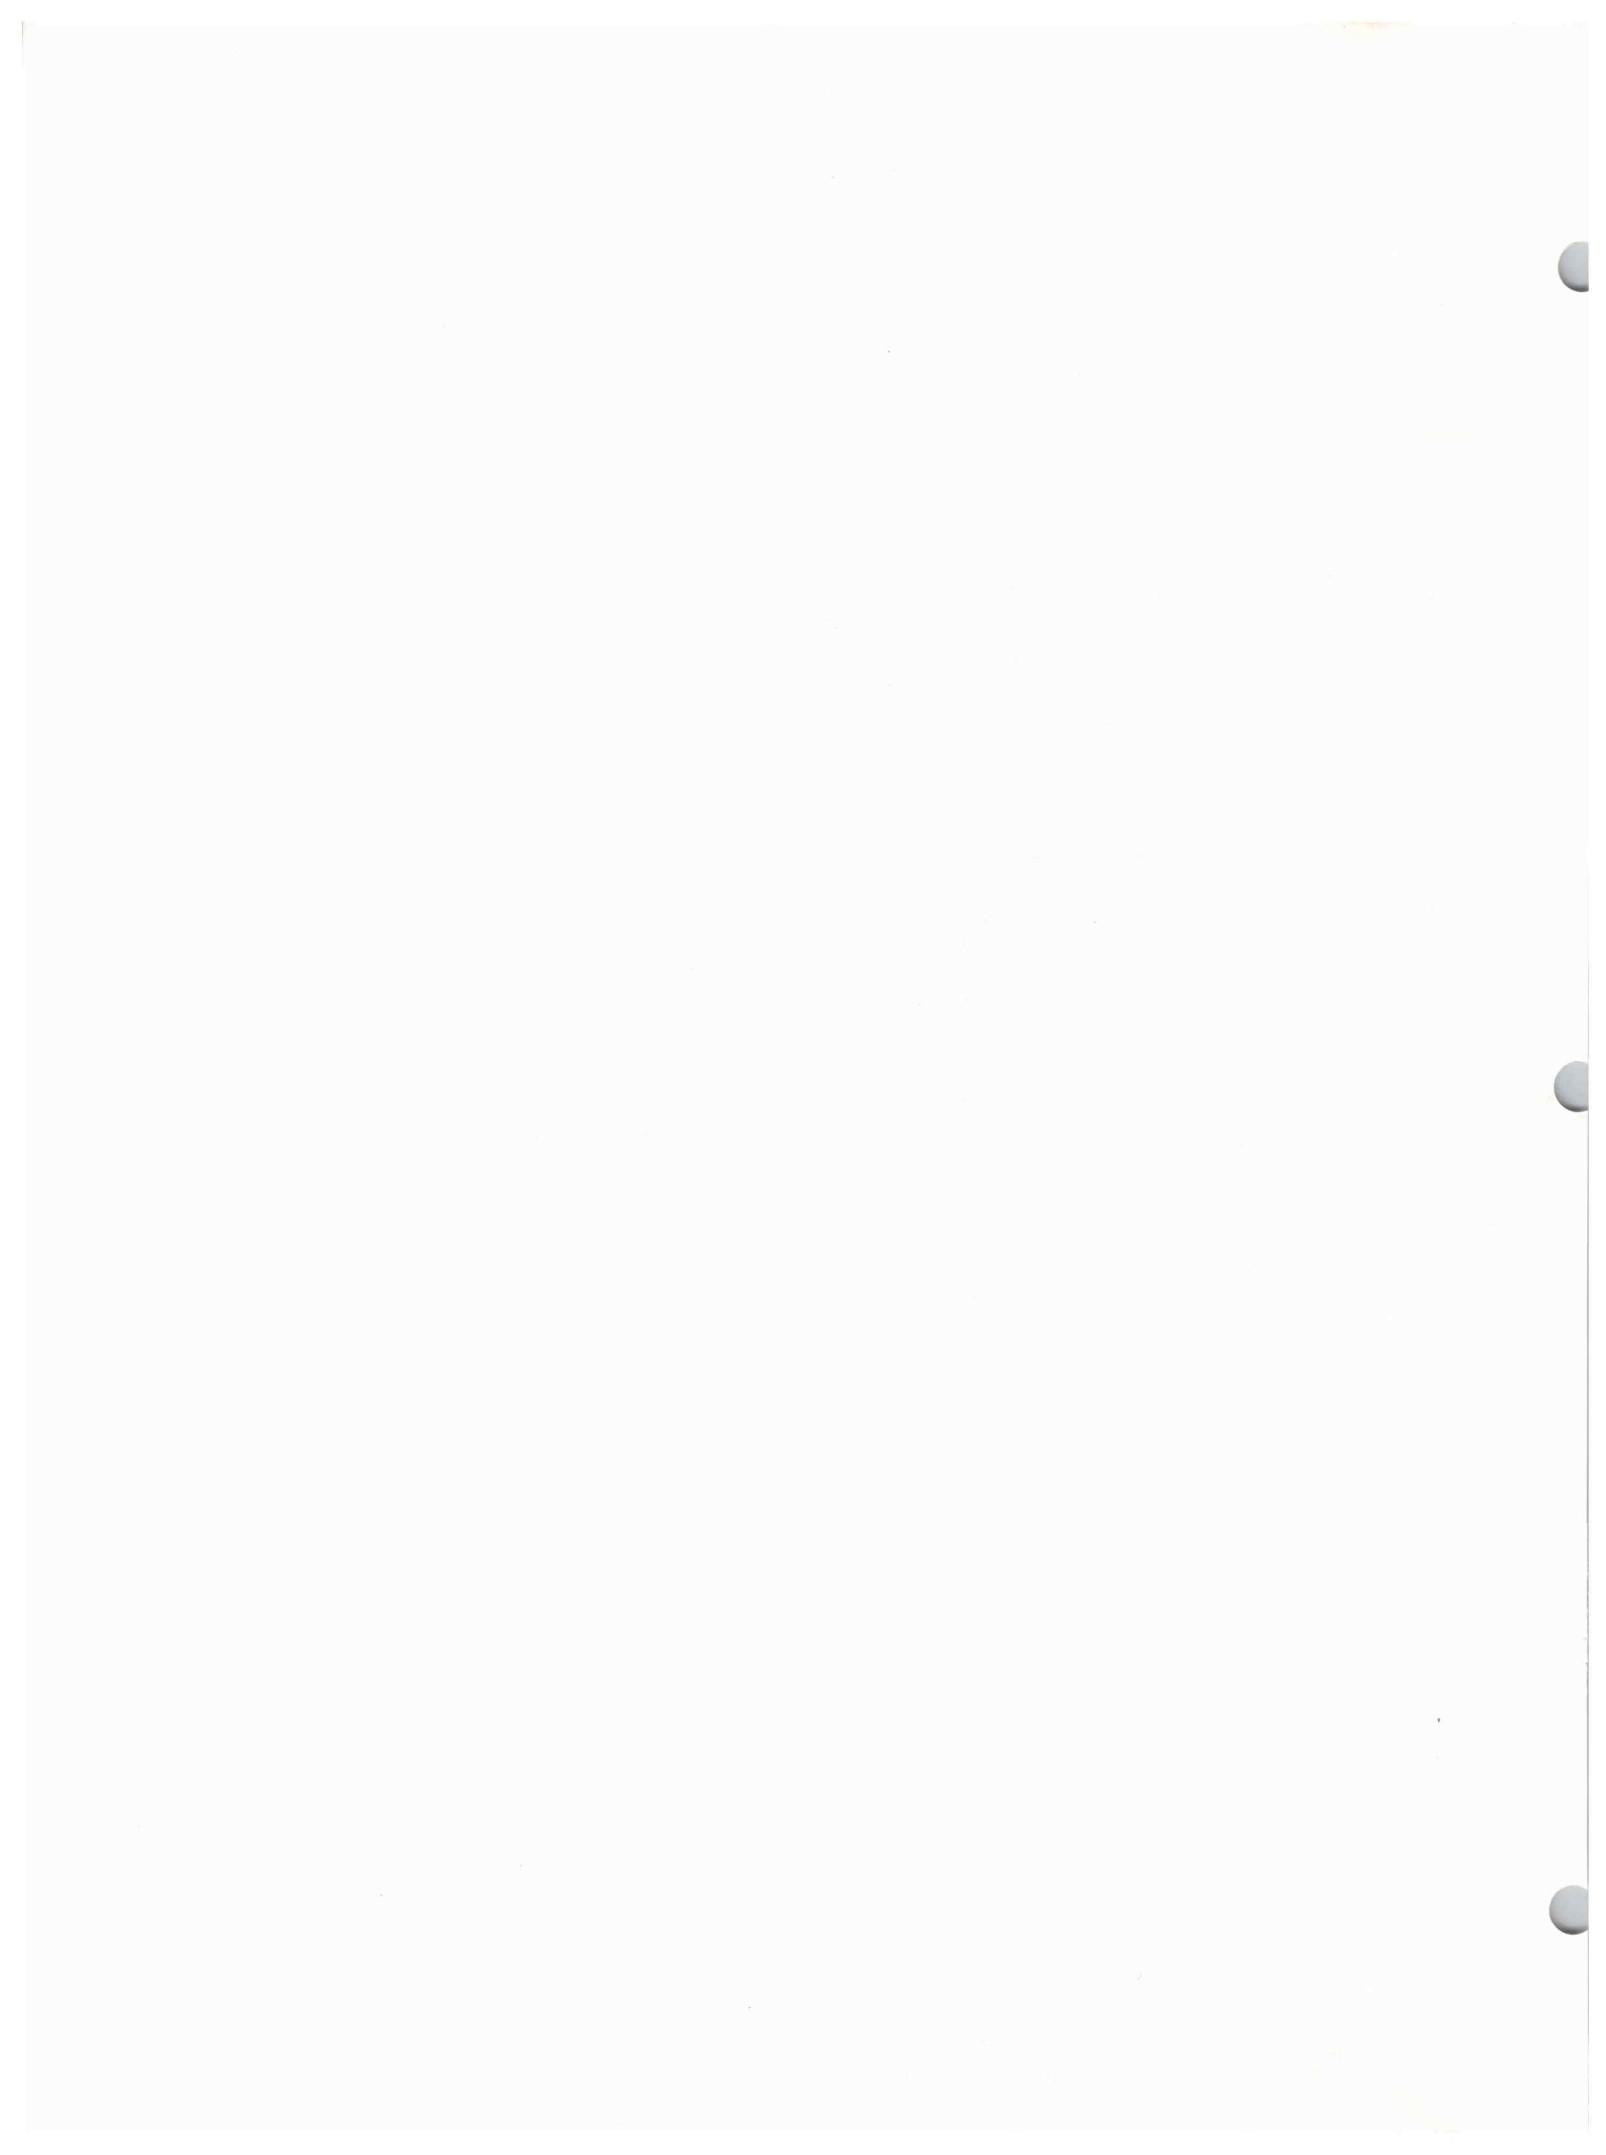

HUG SOFTWARE VOLUME II

NOTE: All BASIC programs in Volume II were prepared with Extended Benton Harbor BASIC 10.02 (Heath model #H8-13). Unless otherwise noted, all programs can be loaded by the command, LOAD "Program Name" or LOAD" ".

Some programs may convert to disk; however, it is the users' responsibility to make whatever modifications necessary.

All questions regarding an individual program should be directed to the author, whose name and address can be found in the Software Catalog and, in some cases, within the program itself.

Additional documentation on some of the programs may be found at the end of the listing.

OVERVIEW

Interactive Data Base (IDB) is a data storage and retrieval system. The data base has a hierarchical organization which allows data to be added, changed, or retrieved with a minimum of effort. The hierarchy can be used in any way desired to store data. For many applications the highest level of the hierarchy will be used to identify the data base and the next level is used to break the data into several logical categories (usually 2-10) that will be beneficial in retrieving the data. The third level in this case could be the data or sub-categories. The data when entered can be single data item or a hierarchy of data items.

Data retrieval is accomplished by "navigating" up, down, and around the hierarchy with a set of commands that are provided with IDB. After each command is executed, data items at the current position are displayed along with all of the data items in the direct path from the top of the hierarchy down to the current position. A "Find" command can be used to locate a data item containing a matching character string. The "Find" command can be used to search data items hierarchically forward from the current position or from the beginning of the hierarchy. The data base may also be listed in an idented outline format if desired. If a hardcopy device is available, the outline format makes a good working document when the computer is not available.

The data base is maintained by commands that add data items, change data items, delete data items, and rearrange data items within the hierarchy.

COMMANDS

This section describes the commands that are provided with IDB. The command syntax rules are:

- 1.) First character must be alphabetic or "?".
- 2.) Second and third character must be numeric if allowed (indicated by "..")
- 3.) Commands that require text type data will prompt for it (E.G. ADD, CHANGE, FIND)

(A..) ADD ITEM

"ADD" will add a data item to the list currently displayed. If a number is entered with the add command the new item will be added after the item specified. To add a data item as the first in the list specify "A0". If no number is specified the item will be added to the end of the list.

(C..) CHANGE ITEM

"CHANGE" will allow the text of the specified item to be replaced.

(L..) GOTO LOWER LEVEL

"LOWER" will move the current position within the hierarchy one level lower on the specified path (data item #).

(H..) GOTO HIGHER LEVEL

"HIGHER" will move the current position within the hierarchy up the path currently displayed by the number of levels specified. The default is one.

(T) TOP

"TOP" will move the current position within the hierarchy to the highest level.

(S..) SELECT FOR MOVE/DELETE

"SELECT" is used to identify a data item that is to be moved to another location within the hierarchy (See (I..) "INSERT") or to identify a data item to be deleted (See (X) "DELETE").

(I..) INSERT SELECTED ITEM

"INSERT" is basically the same as "ADD" but the new data is the data item that was selected with "SELECT".

(X) DELETE SELECTED ITEM

"DELETE" will delete the data item that has been selected with the "SELECT" command. When the the data item is deleted any items at a lower level below the deleted item will move up one level. If a number is specified with the delete command (e.g. X12) that number of data items will be deleted from the hierarchy starting with the data item selected. The multiply delete feature may be disabled if so desired (see section on modifications).

(R) RE-DISPLAY ITEMS

"REDISPLAY" will present the last display of data items again. This command is used if number of data items is greater than screen size on a CRT terminal and a redisplay of the first items is desired.

(?) LIST COMMANDS

"?" is the help function. A list of the available commands is displayed for quick reference.

(O) DISPLAY OUTLINE

"OUTLINE" will display the entire data base in outline format with the data items for each level indented below the owner of those data items on the previous level.

(F1) FIND FIRST MATCH

"FIND FIRST" will prompt for a character string and then starting at the "TOP" searches the data base hierarchically stopping at the first match.

(F) FIND NEXT MATCH

"FIND NEXT" will prompt for a character string (or will use the last string entered if "return" is hit with no character string) and then starting with data item number one of the current display a hierarchical search will be performed stopping at the next match in the data base.

SAMPLE PROGRAM

```
*LOAD "IDB"  
*GET "FARM DATA BASE"

Subroutine Calls	8
Strings	615 (Sample Data Base -- 49 Items)
	<u>5976</u>

* Program text may be reduced by deleteing the following statements;

<u>STATEMENT</u>	<u>BYTES</u>	<u>FUNCTION</u>
1-5	57	Author name and address
1510-1690	372	"HELP" Command
2005-2720	856	"FIND" & "OUTLINE" Commands

OTHER APPLICATIONS

1.) Structured Design (Including Warnier-Orr Diagrams*):

```
PAYROLL PROGRAM
    COMPUTE STATE TAX SUBROUTINE
        IF STATE = "OHIO"
```

```
1)+ THEN
2)+ ELSE
COMMAND-----)
```

*See "Structured Programming with Warnier-Orr Diagrams" by D.A. Higgins
in the December 1977 BYTE Magazine.

2.) Planning

```
BUSINESS PLAN
1978
```

```
1)+ GOALS
2)+ OBJECTIVES
3)+ CRITICAL PROBLEMS
4)+ FINANCIAL REPORT
5)+ CURRENT PROJECTS
COMMAND-----)
```

3.) Family Tree

DOE FAMILY
JOHN DOE 9/5/1942

- 1.) MOTHER: MARY SUE (SMITH) 5/20/1920
- 2.) FATHER: BILL DOE 3/14/1918
- 3.) WIFE: MARY JO (BROWN) 4/17/1944
- 4.)+ CHILDREN
- 5.)+ BIRTHPLACE

4.) Ham Radio Directory

HAM DIRECTORY
USA
K8XXXXXX

- 1.) NAME: BILL JOHNSON
- 2.)+ ADDRESS
- 3.) WIFE: BETTY
- 4.)+ CHILDREN
- 5.)+ BASE: HEATHKIT
- 6.)+ MOBILE: HEATHKIT
- 7.)+ LOG

SUBROUTINES

400 "ADD"/"CHANGE" COMMAND
420 ADD FUNCTION FOR INSERT COMMAND
1050 "SELECT" COMMAND
1200 "INSERT" COMMAND
1300 "DELETE" COMMAND
1500 "HELP" COMMAND
1700 VALIDATE INSERT PATH
2000 "FIND" COMMAND
2400 HIERARCHY SEARCH/DISPLAY OUTLINE
7000 DISPLAY DATA
8000 FIND EMPTY SLOT IN ARRAY
8100 COMMAND INPUT
8500 "LOWER" COMMAND
8600 "HIGHER" COMMAND
8700 PRINT PATH
8800 "TOP" COMMAND

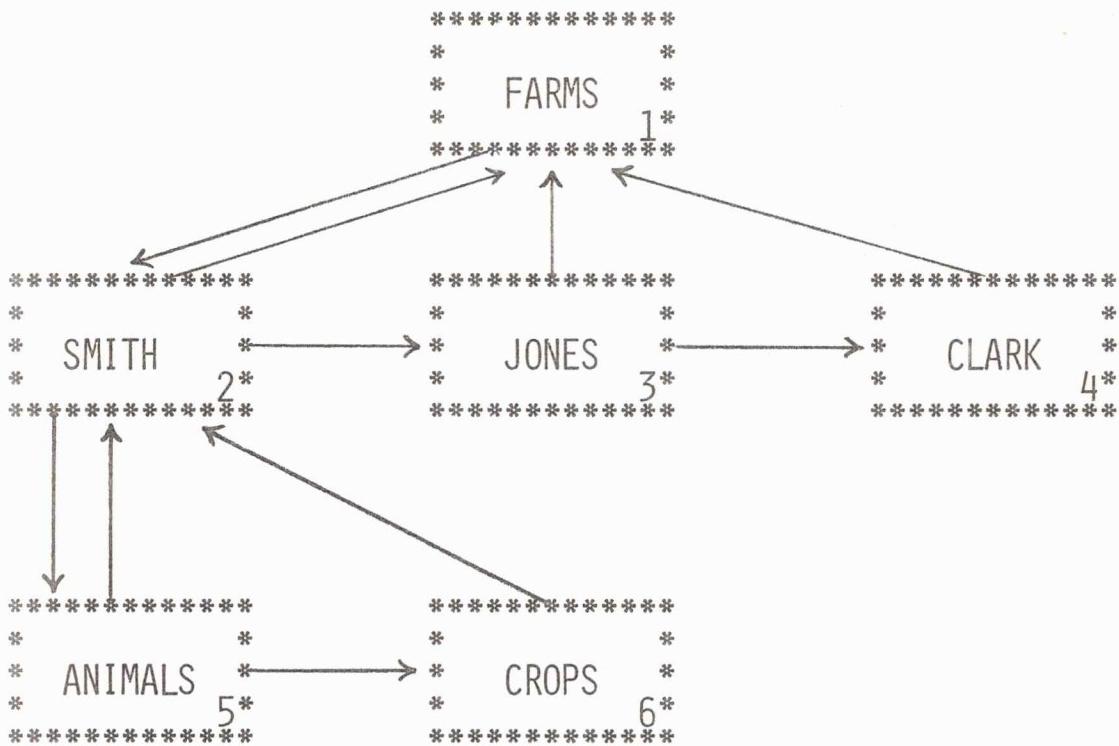

ROUTINES YOU MAY WANT TO MODIFY

<u>STATEMENT #</u>	<u>DESCRIPTION</u>
75-76	<u>FOR HARDCOPY CONSOLE</u> SET B\$ = CHR\$(10)
8280	<u>FOR HARDCOPY CONSOLE</u> GOSUB 7000 CAUSES A REDISPLAY AFTER EACH COMMAND. YOU MAY WANT TO REMOVE IT.
120	<u>DATA BASE SIZE</u> A9 CONTROLS THE MAXIMUM NUMBER OF DATA ITEMS THAT THE DATA BASE CAN CONTAIN. DEFAULT IS 55 FOR A 16K SYSTEM. ADD ABOUT 20 OR 30 FOR EACH ADDITIONAL 1K OVER THE 16K BASE.
105	<u>DATA BASE LEVELS</u> L9 CONTROLS THE MAXIMUM NUMBER OF LEVELS THE DATA BASE CAN CONTAIN.
1468	<u>PAUSE BETWEEN MULTIPLE DELETES</u> DEFAULT PAUSE 800.
1465	<u>DISABLE MULTIPLE DELETE</u> CHANGE TO: GOTO 1499
1510-1690	<u>ADD ADDITIONAL "HELP" INFORMATION</u>
2250 & 2270	<u>CLOCK CONTROL</u> CLOCK IS STOPPED TO HELP PERFORMANCE OF "FIND" COMMAND.
2521	<u>"OUTLINE" INDENTATION</u> INDENTATION IS CONTROLLED BY THE TAB(L5*2). CHANGE THE "2" TO THE INDENTATION AMOUNT DESIRED.
2525	<u>BELL DURING "FIND"</u> DELETE STATEMENT IF THE BELL IS NOT DESIRED.
7035	<u>PRINT LINE PAUSE ON LARGE DISPLAY</u> IF MORE THAN 11 LINES ARE DISPLAYED A PAUSE IS ISSUED BETWEEN PRINT LINES.

VARIABLES

A(A9,3)	ARRAY OF DATA BASE POINTERS
A\$(A9)	ARRAY OF DATA BASE DATA
A9	DIM SIZE OF A() AND A\$()
B\$	STRING OF NEW LINE CHARACTERS USED TO CLEAR SCREEN
C\$	ALPHA CHARACTER OF COMMAND
C2	SELECTED ITEM'S DISPLACEMENT IN ARRAY
C9\$	LAST COMMAND ENTERED
D\$	DATA FOR ADD OR CHANGE
D1	EQUATE FOR DAUGHTER POINTER
L	CURRENT LEVEL WITHIN HIERARCHY
L(L9)	CURRENT PATH WITHIN HIERARCHY
L9	MAXIMUM NUMBER OF LEVELS ALLOWED
M	MOTHER DATA ITEM FOR CURRENT POSITION
M1	EQUATE FOR MOTHER POINTER
N	ARRAY INDEX NUMBER RETURNED FROM "FIND SLOT"
N2	NEXT SLOT "FIND SLOT" WILL CHECK FOR ASSIGNMENT
P1	NUMERIC PORTION OF COMMAND
S\$	STRING DATA TO BE FOUND ON "FIND"
S1	EQUATE FOR SISTER POINTER
S2	ITEM PRECEEDING SELECTED ITEM
T1	NUMBER OF ITEMS TO DELETE ON MULTIPLE DELETE
T2	ITEM NUMBER FOR MULTIPLE DELETE

INTERNAL STRUCTURE

M1 D1 S1

A(1) = 0, 2, 0	A\$(1) = "FARMS"
A(2) = 1, 5, 3	A\$(2) = "SMITH"
A(3) = 1, 16, 4	A\$(3) = "JONES"

FILENAME = I/O ROUTINES - MASUDA

PROGRAM DESCRIPTION

The purpose of this program is to demonstrate to the user one method of handling tape operations on the H8 computer.

The program is actually broken up into three distinct sections. Each section will be covered in detail.

PROGRAMMER:

Richard Masuda
950 Howe Avenue #23
Sacramento CA 95825
1-916-925-8185

CONFIGURATION

Computer:	H8
Memory:	24K RAM
I/O Devices:	H9 Terminal 1 Input Tape Unit 1 Output Tape Unit
Language:	Extended BASIC Version 10.02.01 Utilities PAM-8 Tape Load-Dump Routines

INSTALLATION

The tape supplied has two copies each of Extended BASIC Version 10.02.01 and a BASIC file "I/O Routines".

1. Load BASIC with the PAM-8 loader.
2. Press the "GO" key.
3. Type Load "I/O Routines".
4. Type Continue
The program menu should be displayed.

This program needs at least 260 words above BASIC to work correctly.
The BASIC supplied has been configured with 20K of BASIC and the
upper 4K for user workspace.

MEMORY MAP

<u>DECIMAL</u>	<u>SPLIT</u>	
28680	160 Ø1Ø	Input File Status Byte
28681	16Ø Ø11	Output File Status Byte
28682	16Ø Ø12	Record Type
28683	16Ø Ø13	Record Length
28684	16Ø Ø14	Beginning of Data Block
2894Ø	161 Ø14	End of Data Block
Input Status Byte	Ø	= Closed, 1=Open, 2=EOF Read
Output Status Byte	Ø	= Closed, 1=Open
Record Type	Ø	= Header REC, 1>Data REC, 2=EOF

SECTION I

Lines 10-2116 represent the interactive section of the program. The user has a menu of tape and data functions displayed on the screen and he picks a function he wishes to perform. All functions will be executed the same way a batch program would work except any necessary information is prompted at the terminal.

See the section on function descriptions for a detailed description of each option.

On the tape there is a file names "TEST-MSTR". This tape was created using the interactive section of the program.

CREATING "TEST-MSTR"

Function #1	Open File as Output Enter "TEST-MSTR" for a label (no quotes)
Function #7	Put String Enter "THE VILLAGE" (RET) Enter "483-8148" (RET) Enter "END"
Function #6	Put Number Enter "2681" Enter -1
Function #8	Write Data Record

Repeat 7, 6, 8 for as many records as you want.

After you have entered all the information, you must close the output file

Function #5

A data tape has been created,

Put the tape into the reader and open Input File (#2).

Use Function #11	Read Data REC
Use Function #10	Two Times (2 Strings)
Use Function #9	Once (1 Number)

Close the file when you are finished reviewing the contents.

"TEST-MSTR" FILE CONTENTS

A/N	A/N	N
#1 The Village	483-8148	2681
#2 Classic Cabinets	922-6029	1229
#3 Fort Sutter Hearing Aid Centers	966-0336	2724
#4 ABC Company	462-8122	1874
#5 The Electric Company	821-4211	1643
#6 Pacific Gas and Electric	926-8102	1401
#7 EOF Record		

SECTION II

This section will read the "TEST-MSTR" created on the tape and display it on the terminal. The program is included to show how a batch mode program might work.

To Run

Get to the command level

Ready the tape with the tape at 125 according to the tape indicator.

*GOTO 5000
*Continue

The program will print a listing of the tape similar to the listing at the end of Section I.

TEST-MSTR LISTING PROGRAM

Read A Data Record	6444Ø	

TAPE FUNCTION DESCRIPTIONS

Open File As Output

The tape output file must be opened before the program can write to tape.

The routine expects a file label to be in Y\$. For example, `10 Y$="TEST-MSTR"` would write the string "TEST-MSTR" as the header record for the file. The label may be up to 256 allowable characters long.

If the file is already open upon entering the routine, an error results and the program aborts.

Open File As Input

The tape input file must be opened before the program can read from tape.

The routine expects a file label to be in X\$. For example, `10 X$="TEST-MSTR"` would tell the program that the first record on the tape should contain "TEST-MSTR".

If the label provided by the user does not match the label on the tape, the program will display a message (continue? Y/N).

If the user puts a "Y", the program will ignore the label error and continue. Otherwise the program will abort.

If the file is already open upon entering the routine, an error results and the program aborts.

Open File As Extend

This routine will

1. Open the input file.
2. Open the output file.
3. Copy all of the records from the input file to the output file.
4. NOT write the EOF record to the output file.
5. Close the input file.
6. Returns control to the user.

Because of the sequential nature of tapes, this function allows the user to append data to the original file.

The user is responsible for closing the output file.

If a label error occurs, the label provided by the user will be used on the output file.

Close The Input File

When the user invokes this function, a zero is stored in the input file status byte to indicate that no more data is available from the input tape.

If the file is already closed, an error results and the program aborts.

Close Output File

When the output file is closed, three (3) things happen:

1. A check is made to make sure the file was not already closed. If the file is already closed, an error occurs and the program aborts.
 2. A record containing the string "1EOF-H8" is written to tape.
 3. The output file status byte is set to indicate that writes to the output file are no longer valid.
-

Put A Number and Put A String

These routines allow the user to format data into the output record. In both cases, a check is made to make sure that a 255 character maximum is maintained.

When 'Put A Number' is called, the number is converted into ASCII characters and appended to the output record string. One (1) character of control information is also appended. (file separator CHAR\$(28))

When 'Put A String' is called, the string and it's control character is appended to the output record string. Control information consists of the group separator CHR\$(29).

The format of the output record will be:

FS/N₁/FS/N₂/GS/S₁ -----GS/S_n/FS/N_n/ETX

Where FS = file separator character preceding all numeric fields.

GS = group separator character preceding all string fields.

ETX = end of text character.

Put number expects a value in Y.

Put string expects a string value in Y\$.

Write A Data Record

After the user has 'PUT' his numbers and strings, he may write a data record. This routine actually writes the data to tape (assuming the output file is open).

Get A Number and Get A String

The opposite of putting a number/string is

'GET'ting a number or string.

Using this routine the program will decode the input record string and make available the next value.

When 'GET' a number is called, the program will return the value in X.

When 'GET' a string is called, the program will return the value in X\$.

In both cases, a check is made for 'GET'ting the correct type of variable.

If you call 'GET' number and a string value is the next element an error will result and the program aborts.

The order in which the user should 'GET' variable should be the same order as how the programmer had 'PUT' the variables.

Read A Data Record

After the user has opened the input file, data records may be read. This routine makes data available to the program to 'GET' strings or variables.

An error occurs if the user attempts to read past end-of-file, or read from a closed file.

ERROR MESSAGES

Attempting to close a file that was not opened

A file must be opened before a close command can be executed - check program Logic.

Attempting to 'GET' a string/number before a read

The user is attempting to extract data from the input record before any data way made available to the program.

Attempting to read from an unopened file

The user must open the input file before a read data record can be performed.

Attempting to read past end of file

The user has failed to check properly for the end of file condition. End of file exists when PEEK(28680)=2. Another read should not be performed after the byte is set to 2.

Attempted write to an unopened file

The user must first execute an 'Open Output File' routine to initialize the header REC.

Header label not found

The first detected record was not a header record on the input tape. Check for proper positioning of the tape.

Note: Only tapes created from the program output routine should be used as input to another or the same program.

Input file already opened

The user is attempting to open the input file without an intervening close statement.

Label error - Label found = NN

The label the user has specified does not match the label on the tape. 'NN' specifies what the open routine found on the tape. The user will be asked if he wishes to continue. Only a 'Y' response will be accepted in order to continue. All other responses will result in the program aborting.

Maximum record length exceeded

The sum of all the characters has exceeded 255 characters.

Note: The 255 character limit applies to all control characters embedded within the output record.

Output file already opened

The user has attempted to open the output file without an intervening 'CLSOE OUTPUT FILE' command.

Type conflict exists

Two conditions can cause this message.

1. The user has requested a 'GET' string and a numeric field is next or he has requested a 'GET' number and a string field was next.
2. The user has requested a 'GET' string or 'GET' number and there are no remaining fields left in the input string area. The user should check the format specified against the tape format.

FILEMAINT/MULTISORT

Roseman

The file maintenance system enables the user to create, update and sort a file placed on tape. The system consists of two programs, FILEMAINT and MULTISORT. The sort is run as a separate program in order to make as much memory available to it as possible.

The tape I/O routines are those of Mr. Bellinger* (to whom I will be forever grateful). While these routines are rather slow, they do seem to work quite well. They offer program controlled sequential I/O operations on files too large to be read into memory.

When you run the FILEMAINT program you are asked which of four options you desire. The options are:

1. Establish new file.
2. Insert additional items to an existing file.
3. Make changes or deletions to an existing file.
4. List out an existing file. A message is generated requesting entry of the option desired.

Each option operates as follows:

1. ESTABLISH NEW FILE

A message is generated requesting the number of fields desired in the record and the name of each field. Following these entries you will be directed to ready an output tape (please use a clean one), and press space bar when ready.

The program will now accept entries to the record. You will be prompted in these entries by the names previously supplied to the program.

After entering the last data field in the record you are asked to check it for mistakes. Press return if record is OK. If you discover that you entered some wrong information you simply key in the number of the data field in error and reenter the data. Again you will be asked is the record is OK; if it is, hit carriage return and the record is written out to tape in the following format:

/DATA1/DATA2/DATA3/ - - - - - /DATA_n

* REMark Issue #3, page 3 and 11

The slashes are used as delineators. Note that the total length of a record cannot exceed 256 characters including slashes.

The system now asks if you are finished. If not, you are again prompted to enter a new record. If you are finished, the system writes a trailer record to the tape file. The trailer record consists of an asterisk (*). After the trailer is written, the program asks if you wish to continue using the FILEMAINT system. At this point I usually like to take a look at the file and check it for errors. (I suspect my real motive is just to admire it.) If you wish to look at the file, select option number four (4).

2. INSERT ADDITIONAL ITEMS TO AN EXISTING FILE

When this option is selected you are instructed to ready an input and output tape and to press the space bar when ready. The system then proceeds to read each record off the input tape and write it to the output tape. When the end of file trailer is detected on the input tape, the program reverts to the same routine it used in option number one (1) where you first established the file.

You are asked to name the input fields so the system can prompt you through your entries. However, you are not required to input the number of data fields because the system has already established this while it read the input file, i.e., all records in the file must have the same number of data fields; a count of slashes in any given record determines the number of fields for all records. As in option number one (1), the records are written to the output tape as you enter and verify them. After each record entry, you are asked to determine whether or not you are finished or wish to continue.

3. MAKE CHANGES OR DELETIONS TO AN EXISTING FILE

This option invokes a very flexible routine which allows you to correct or delete entire records or only certain fields within the records or any combination of the above.

When you choose this option, you are asked to enter the field number to be used as the search argument. Next you must enter the search argument itself. You are then asked to mount tapes and to press space bar when ready. The input tape is read and the content of the field you selected is compared against the search argument you entered. If they are not equal then the record is written to output tape and a new record is read from the input tape. The above procedure is repeated until the proper record is found. When the record to be corrected is found, it is printed out and you are asked to enter the field number to be corrected or to enter zero (0) to delete or correct the whole record. Assuming you enter (0), you are then asked to hit carriage return to delete the record or to reenter the entire record. If you select a field number, you are then asked to reenter the field. In either case, the system asks if you are finished with corrections to this record. If so, the changed record is written to the output tape; if not, you are again asked to enter a field number and the procedure is repeated. Once the record has been written to the output tape, a prompt will ask whether or not you desire to make any more changes.

If your file is already sorted (e.g., on last name) then you can save time by entering your corrections in the same order. If desired, the program will continue to search the input tape for additional records to be corrected or deleted. When no more changes are to be made, the remaining input records are written to the output tape.

4. LIST OUT AN EXISTING FILE

When this option is chosen, you are instructed to ready the input tape and press the space bar when ready. The program reads the input tape and lists it out record by record, i.e., read record, print record, read record, print record, etc. When the file trailer (*) is encountered, you are again asked if you desire to end or continue. Prompts direct proper responses for the end or continue function. Tape copies can also be made using this option.

GENERAL PROGRAM COMMENTS:

1. In order to use Bellinger's tape I/O routines, it is necessary that BASIC be reconfigured so that the "HIGH MEMORY" limit is lowered 256 bytes. The author's system presently has 20K (HIGH MEMORY = 28672), just to be on the safe side I lowered it 300 bytes to 28372. Statement #100 in the program listing should be changed to the user's reconfigured high memory limit.
2. FILEMAINT was written in EXTENDED BASIC Rec. 10.02.01. In this revision, USRFCN is located in memory positions 17990 and 17991. If the user has a different revision, then statement #65010, 65020, 65180 and 65190 must be changed to that revisions USRFCN address (in decimal). The USRFCN address can be found in the table at the rear of the BASIC manual.

The second part of the FILEMAINT system is a program which enables the user to sort the tape file created by the FILEMAINT program. In using the MULTISORT program, up to ten (10) sort fields can be specified. These fields are specified from major to minor, for example, in the record below suppose we wish to sort on salary by group in a given region. We enter the sort fields as 5NA, 7NA, 3ND (where A is for ascending and D is for descending).

```
#1      #2      #3      #4      #5      #6      #7  
/LAST NAME/FIRST NAME/SALARY/ADDRESS/REGION/SSN/GROUP
```

The sort operates as follows:

1. The user is asked to input the number of records in the input file. This may be overestimated but should never be underestimated. Try not to overestimate too much as this costs memory.
2. The next input is the number of fields to be sorted on. In the example above, this would be three (3).
3. Now the field numbers are input one at a time. Again in the example, these would be 5NA,7NA,3ND.

4. The program now asks you to ready the input tape and to press the space bar when ready.
5. As the program reads the input tape, it builds a table in memory containing only the data contained in the sort fields of each record and the record number. NOTE: If this table exceeds your available memory, then the sort cannot be run. In this case you must reduce the number of sort fields specified in (2) above.
6. The above table is now sorted.
7. The program next asks you to ready an output tape and to press the space bar when ready.
8. The program predetermines the number of whole records it can read into memory. It does this by dividing your available memory by an average record length which was determined during the first pass of the input tape. The number of records on the input tape was also determined during the first pass. The number of records on the input tape is divided by the estimated number of whole records that can be read into memory to determine the minimum number of passes of the input tape that will be required to complete the sort. The minimum number of passes is then printed out.
9. You are now asked to rewind the input tape and ready it to be read again.
10. The program now tries to match records off the input tape against the sorted table. When a match is found, the record is placed in memory. This process continues until we run short of memory or we encounter an end of file (*).
11. The table of matching records is now written to the output tape and the user is again asked to rewind the input tape for the next pass. This process continues until we satisfy all records in the sorted table. The same general program comments apply to this program as to FILEMAINT.

FILEMAINT/MULTISORT

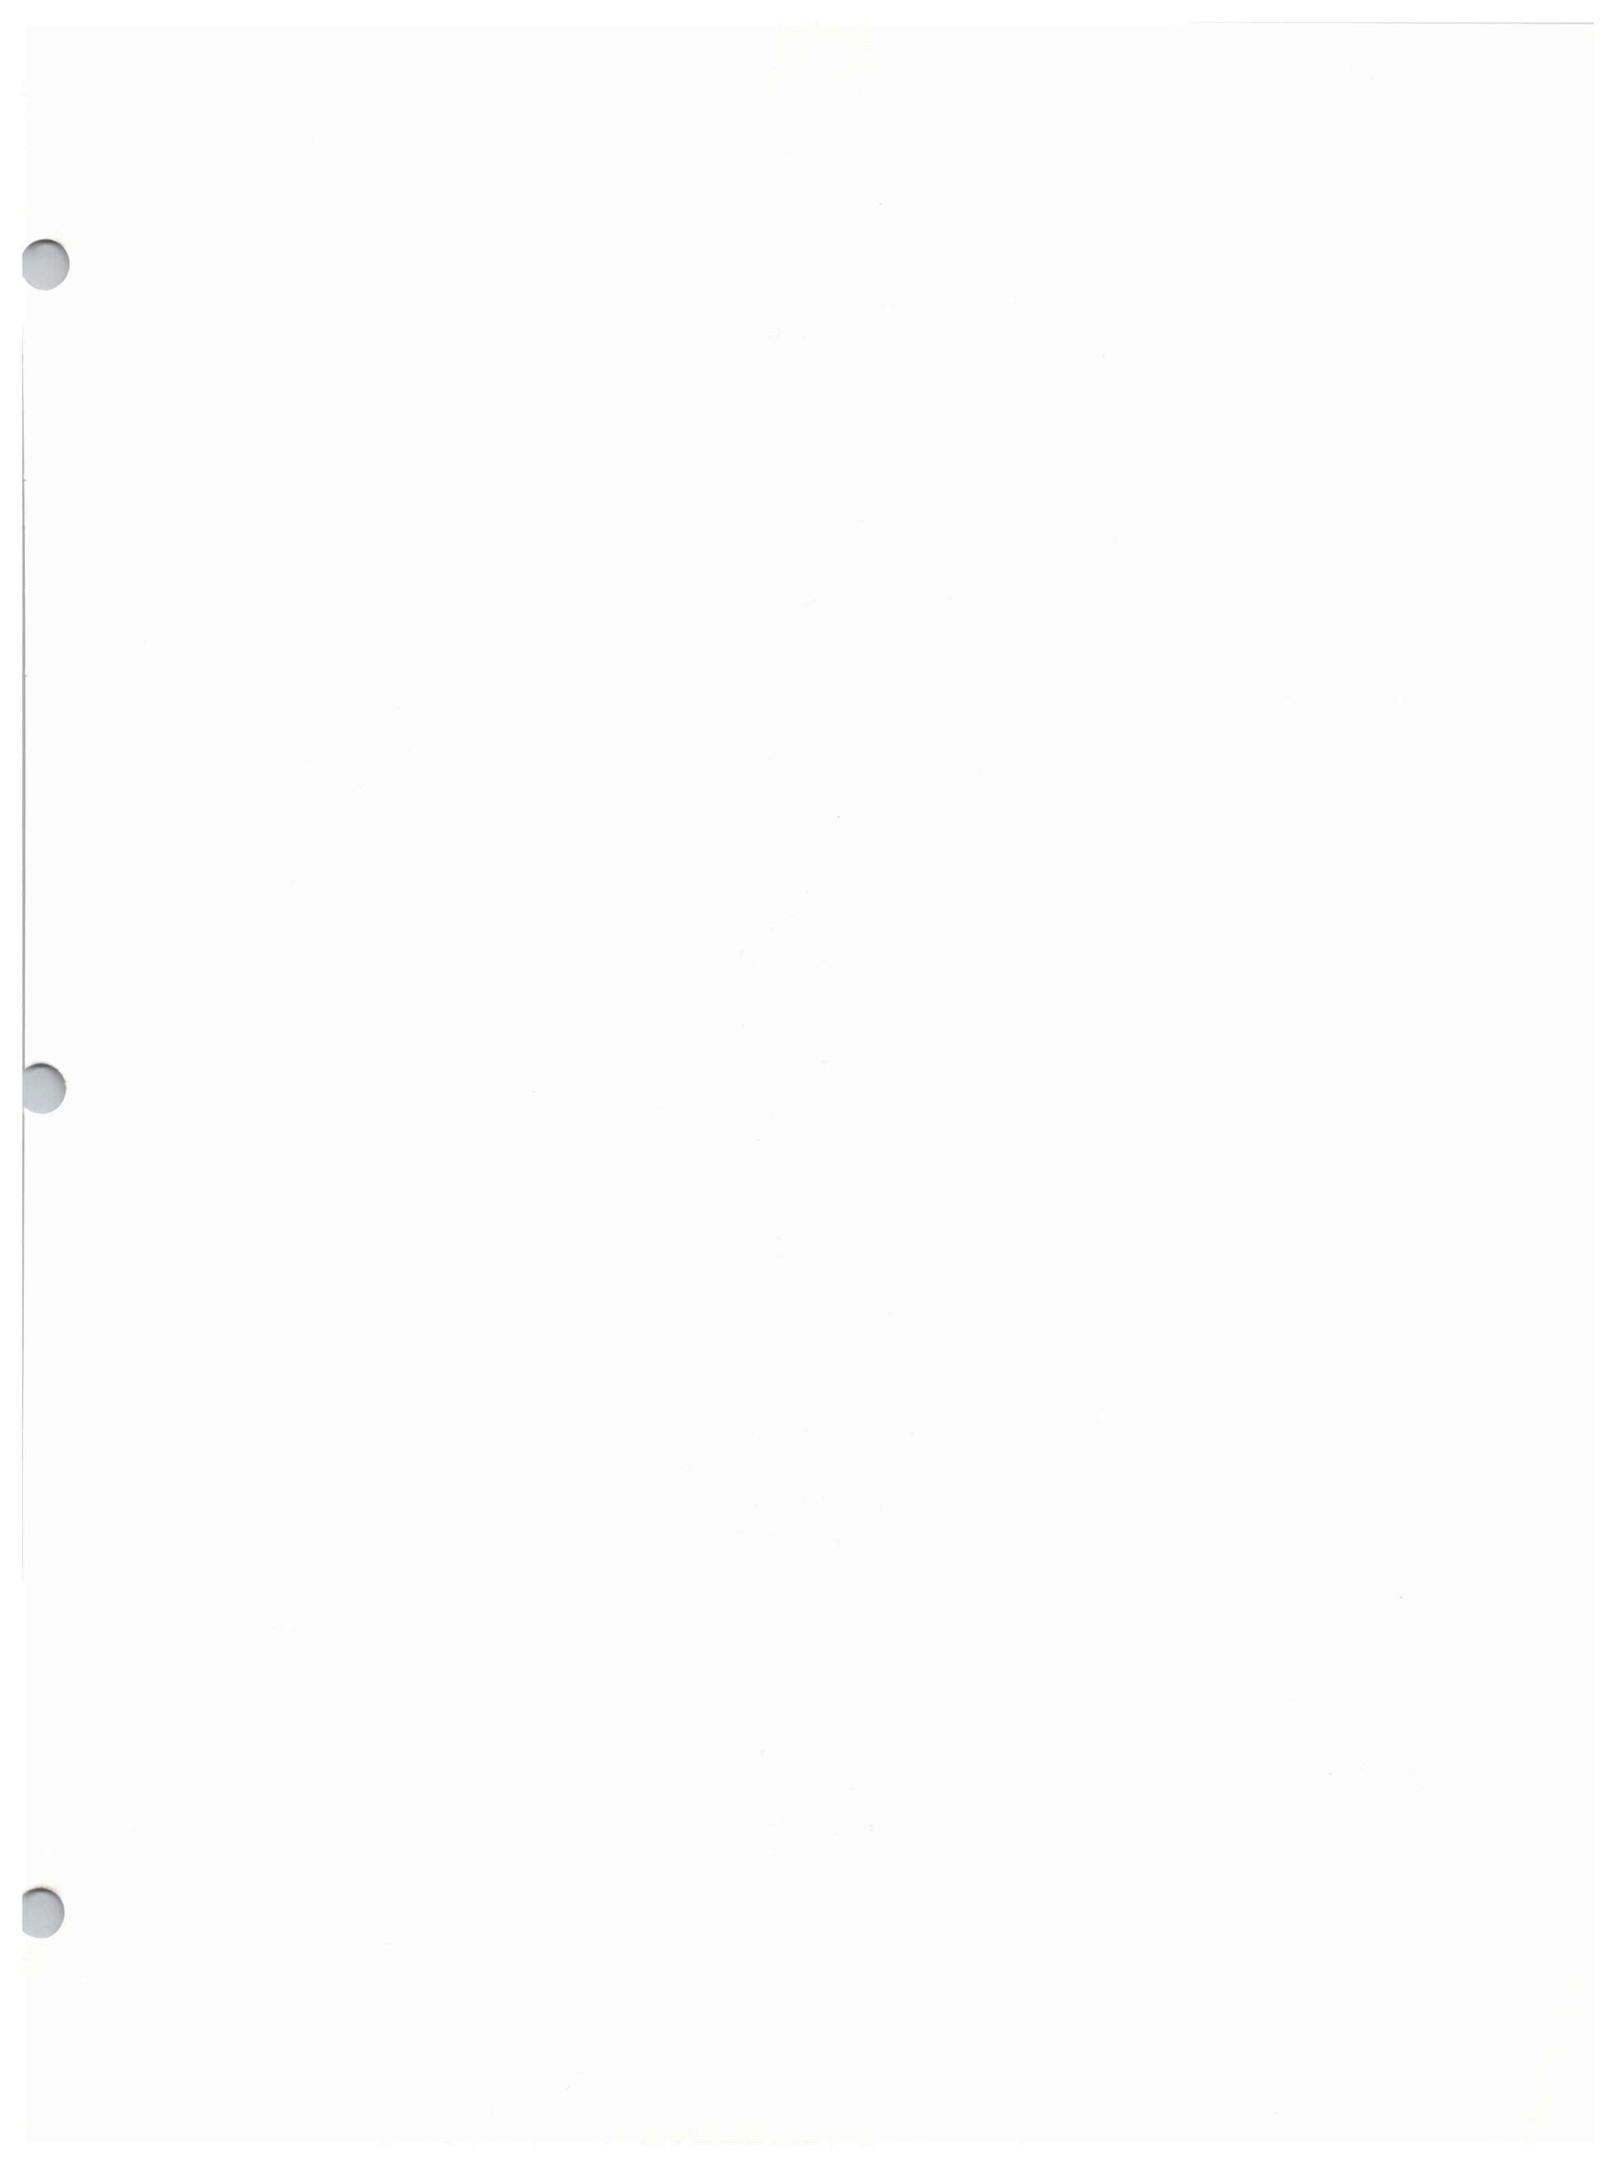

Roseman

Hardware requirements for this system are:

H8 with 16K

Terminal

Two (2) tape recorders

MULTIPLE FILE MANAGEMENT

Hicks

AUTHORS NOTES

The program is "file management" oriented for the purpose of allowing the user to create his own data files, such as a cancelled check register, name and telephone/address directory, customer and account file, or a hundred other uses that I leave up to the user's imagination and personal needs.

Unlike other such file management programs I have come across, this program is not restricted to the number of columns available for the user's data information. A choice is available in the program run from just 1 column, all the way up to 20 columns, or more (with a simple modification of a program line).

WARNING! THIS PROGRAM SELF-DESTRUCTS WHEN RUN!!

Once the user has completed the program instructions, these portions of the written program become useless and only take up valuable memory space that could otherwise be used for data by the user. Therefore, thanks to Robert Behar and Neal Rogers (REMark Issue #3), I have not only incorporated the 'Put' and 'Get' into the RUNning program, I have included the 'Delete' command.

The program is designed to free the user of the burden and necessity to modify, rewrite, and de-bug, a program in its entirety just because an existing program is restricted to 4 columns and he would like 5 columns, 8 columns, or whatever.

The "master" program contains no such restrictions since the variable specifications are contained in the individually created DATA files. The "original" program is only required when the user wants to create a new data file with different column requirements, title, and column names. Once a new data file is created, the remaining program is always a "master" program that is compatible with any previous data files created.

The program is further designed so that all data entered is "string" data since the program is, after all, a "file" and has no number-crunching requirements. The exclusive use of "string" data consumes massive amounts of memory, especially on large data file programs, but cannot be avoided without creating substantial restriction on the user by designating some columns as "numbers only" to conserve string and memory space.

Due to the ease in which a user can create a data file and its related column headings, this program could possibly be used as a "creative tool" to design the print format of a large program before an individual program is written in final form.

THE 'INTELLIGENT' DISASSEMBLER

By: Jim Warner
10121 Hyway 55
Plymouth MA 55441

OK, so maybe we don't need another 8080 disassembler. It's true that the second issue of REMark contained a disassembler program which could serve us very well. But frankly, I've been intrigued with the concept of a disassembler almost since the day I first keyed in and successfully ran the Heath initial test routine.

I remember that event very clearly. It took place at 4:00 a.m. after working 'round the clock' completing the front panel board. What a thrill to realize for the first time that here was my very own computer — and it was actually doing something! My excitement increased as each new Heath distribution tape was loaded and run. Now my computer was not only doing something, but it was doing something useful. Of course, that realization brought a flood of questions, mostly of the "wow, how does it do that?" variety.

Not being one to leave such questions unanswered, I set about to create a disassembler, in assembly language no less. Believe me, there's no better way to learn a new computer language than to tackle such a project. After several weeks, I had my first version up and "sometimes" running. It was a modest beginning. This disassembler was only capable of absolute disassembly. There were no provisions for symbolic labels and I frequently encountered the situation where data was being misinterpreted as instructions. Wouldn't it be nice, I thought, if the disassembler could make that distinction. I mean if I was able to apply standards of reasonableness to what I watched being disassembled, why couldn't he? That way he'd know that at a particular memory location was an ASCII "1", not a load stack pointer immediate instruction.

The 8080 instruction set contains a mere 245 separate instructions. Thus, of the 256 different bit configurations possible in an 8-bit byte, only 11 combinations constitute a non-instruction. And even those non-instructions could be valid as the second or third byte of a multi-byte instruction. So, we have a situation where virtually any random memory location would generate what looked like a valid 8080 instruction. Yet we know that a good portion of a computer program is really data — tables and literals.

At last, here was a project worthy of my attention — a clearly impossible task! I would create an "intelligent" disassembler, one which was capable of distinguishing between object program logic (instructions) and object program data. It would assign default labels to program and data segments plus provide for user designated labels as well. Its output would be acceptable input to the text editor (TED-8) for potential modification as well as the assembler (HASL-8) for re-assembly.

After investing many weeks in pursuit of this glorious hunk of software, it began to appear as though the task was indeed impossible. Version after longer, more patched version crashed and proved very difficult to debug. The need for frequent revisions along with the subsequent lengthly assemblies clearly suggested flaws in my original design. And these flaws prevented me from ever actually testing my key algorithms — those dealing with symbol table manipulation and access. My dream was slipping away! What I desperately needed was a means to make program modifications quickly and painlessly. I also needed a powerful run-time package which could monitor or alter program activity on the fly. Hey, wait a minute. What I needed was the Extended Benton Harbor BASIC interpreter!

Though I remain the type of person who likes the informal title of "assembly language programmer", my BASIC interpreter will never again be thought of in terms of last resort. Rather, it will be thought of as perhaps the best means of prototyping any complex task. I, therefore, offer this BASIC program as a permanent reminder to me, and a suggestion to other readers, of the power and flexibility of this sometimes snubbed high level language. And, I might add as an example of the latest Extended BASIC with data base capabilities.

So, before I get back to HASL-8 with this BASIC prototype to use as a model in developing my faster, more efficient assembly language version, let me share with you its inner workings. I think you'll find that this is not just another disassembler.

GENERAL BACKGROUND

The "intelligent" disassembler is designed to run under Extended Benton Harbor BASIC version 10.02.01. It consists of program text and a data base. The program text occupies approximately 6500 bytes of memory, but can be reduced to less than 5000 by deleting the REMark statements, all of which are dispensable without additional modification. The data base will occupy additional memory, but its size is variable — more on that later.

After an **FLOAD**, the **CONTINUE** command will result in an identification heading followed by a "START?" prompt. This invites the disassembly start address. All disassembler addresses are in offset octal format and require a full 6 digits, including leading zeros. The same is true of the "END?" prompt which follows a valid start designation.

After the disassembly range has been established, the "MODE?" prompt is printed. There are two distinct modes of operation under this disassembler ("SYMBOLIC" and "ABSOLUTE") and these are the only valid responses.

ABSOLUTE MODE

When this mode is specified, the next prompt is "FLAG?". Any single character input at this point will be used to alert you when disassembly has or might become suspect — when instructions are encountered which may signal a data area instead. For a description of such instruction types (in this case types #3-6), see Table 1.

The final prompt will be an invitation to configure your terminal and type Return. In the absolute mode the disassembler formats the print line so as to take advantage of Heath's H9 Short Form provision. In this way a larger area of memory can be displayed at any given time.

Each disassembled line is preceded by the octal representation of the low order byte of the current memory location. In some cases this prefix will also display your designated "flag." When page boundaries change (the high order byte of the current memory location) an additional line will be generated to so indicate.

At any point during the disassembly range, a CTL-B will result in a termination of the current process and the "P=" prompt will be printed. This is an invitation to alter the disassembler's current memory pointer (again in offset octal format) so as to advance or back up the disassembly process. This can be a convenient way to investigate a subroutine following a "CALL" instruction. When you wish to resume the abandoned memory location, another CTL-B followed by the new address will accomplish it.

SYMBOLIC MODE

When this mode is specified, the next prompt following the mode designation is "VALID LO '/' HI?". We'll discuss the reason for this later. For now suffice it to say that this requires two offset octal addresses separated by a slash (/). Depending on the length of your disassembly, the next prompt could be some time arriving. However, here's what you will see at the terminal, at varying times of course.

PASS ONE IN PROGRESS . . .

SYMBOL TABLE EVALUATION IN PROGRESS . . .

SYMBOL TABLE LABEL ASSIGNMENT IN PROGRESS . . .

FINAL PASS BEGINNING. CONFIGURE TERMINAL.
TYPE CR:"

Since we will talk about each phase in detail, at this point let me just briefly cover the symbolic CTL-B options.

By typing CTL-B just prior to the final pass, the disassembler will print the symbol table, including addresses and labels, for you to review. A second CTL-B while such a review is in progress will terminate the printout and return you to the configure terminal prompt. This process can be repeated unendingly if you desire.

DATA BASE (DRIVING TABLES)

The intelligent disassembler data base consists of several items — minus the symbol table. It is up to each user to dimension the symbol table to whatever size memory will support. This is accomplished by using the "DIM S\$(xxx)" in the command mode. Care must be taken to leave room for the growth of the symbol table entries also. Thereafter, assuming the program is saved at this point (FDUMP), the data base would consist of T\$(255), T(4), N\$, S\$(xxx).

The string variable N\$ is simply an error note. Its value can easily be changed in the command mode. To find out how it's used, you might try a "SYMBOLIC" disassembly with a start of 000256 and an end of 000264. For this experiment you may specify any "VALID LO '/' HI" addresses.

The small numeric array T is used only during symbol table evaluation. Its elements are zero at this point.

The large string array T\$ represents the primary disassembler table. Unlike the other members of the data base, it is crucial to both disassembly modes.

This table enables the disassembler to produce octal values, determine instruction lengths and types and print the mnemonic operation codes. It consists of variable length entries which contain the following information:

LEFT\$(T\$(x),3) = Octal equivalent of x

MID\$(T\$(x),4,1) = 8080 instruction length

MID\$(T\$(x),5,1) = Disassembler instruction type

MID\$(T\$(x),6) = 8080 operation code

Thus the entry for T\$(205) would appear literally as "31531CALL" while the entry for T\$(1) would look like "00132LXI B."

This should be fairly self-explanatory and its need vary apparent. For a more thorough review of the primary table, you might wish to issue the following immediate command after you LOAD:

```
FOR I=0 TO 255: PRINT LEFT$(T$(I),3) " "
MID$(T$(I),4,1)
```

```
" " MID$(T$(I),5,1) " " MID$(T$(I),6): NEXT I
```

Hit the Short Form button then Erase before you key Return, use CTL-S & Q to govern scrolling and review the primary table 'til your hearts content.

THEORY OF SYMBOLIC OPERATION

We know that the CPU will execute instructions sequentially within a given block of memory until told to do otherwise. One way to accomplish that "otherwise" is through the use of a branch type instruction. Examples of assembly language branches would be "CALL (address)" and "JZ (address)". The equivalent BASIC statements would read "GOSUB (line #)" and "IF Z=0 GOTO (line #)".

There is one other type of instruction which affects the sequential nature of program execution. This is the instruction through which processing cannot pass. JMP, RET and PCHL fall into this category and constitute the only such instructions in the 8080 instruction set. As far as the CPU is concerned, the only way processing could proceed beyond these points is if the address was reached through a branch instruction found elsewhere in the object program.

A disassembler which could assign symbolic labels to the addresses generated by these two types of instructions would have taken a big step toward "intelligent" disassembly.

PASS ONE (SYMBOL TABLE CREATION)

As we sequentially disassemble an area of memory, let's ask our disassembler to construct a table. In its inception it will be primarily an address table, one whose entries consist of addresses. However, it will eventually become our symbol table and, since that name sounds so much more impressive (and will later be more accurate), you'll hear me refer to it more often as such.

This table will contain variable length entries of the format:

LEFT\$(S\$(x),1) = Evaluation flag

MID\$(S\$(x),2,6) = Address

MID\$(S\$(x),8) = Type references/Lable

We'll insert the address of all branch objects (instruction type #1) into this table. While we're at it, let's also insert the address of all load objects (instruction type #2) into our table. Although such instructions do not affect the sequential nature of program execution, they may give a hint of a potential data pocket. Finally, we will take the address following those instructions through which processing cannot pass (current location + instruction length), these are instruction type #4, and place it in our table as well. These deferred impact instructions provide an even stronger hint of potential data pockets within the disassembled program.

Incidentally, the job of building this symbol table will be made easier if the entries are always kept in ascending order with no duplication. Such is the case with my BASIC disassembler. For the technique used, I direct your attention to lines 55000-55900 of the BASIC listing. You'll notice that element zero, S\$(0), is used to hold the total number of entries currently in the table. It will be incremented whenever a new address is added, whether that address is inserted within the table or appended to the end of the table (depending on its value). Existing entries are simply updated with the new reference type. In this way we can main-

tain a history of how many references were made to a particular entry and, more importantly, in what ways that address was used in the disassembled program.

All right, we've completed the first pass. A block of memory has been sequentially disassembled and assumed to have consisted entirely of instructions — no data. In the process we created a table of addresses. Have we done enough? Well, we've done enough if all we want is the ability to assign symbolic labels to the disassembled listing. Unfortunately, our disassembler is still "dumb" and would merrily treat data as instructions. We must now ask him to analyze those table entries and, where appropriate, re-disassemble certain object program segments. In fact, we'll find that some areas of a program must be re-disassembled (disassembled for a third time) if this guy is to acquire real intelligence.

SYMBOL TABLE EVALUATION

In the evaluation phase, we can ignore all addresses in our symbol table which are less than the disassembly start address or greater than the disassembly end address. Such entries will be considered "external" and we won't try to classify them as pointing to data or instructions. Next, we can ignore all branch object addresses. We'll assume that the author of whatever it is we are disassembling wouldn't have directed the CPU to execute a table or literal pool (in other words data). Now you can see why it's important that each entry in the symbol table also provide an indication of how that address was used in the disassembled program.

Having ignored what is probably the majority of entries in our symbol table, what do we have left? We are left to consider only those addresses which were used in a load instruction (type #2) and those addresses generated by the disassembler because processing could not pass through the previous instruction (types #4 & #5). Remember also that these remainin entries will fall within the range of our disassembly, having ignored external references.

At this point, any further disassembly will be controlled by the addresses contained in the symbol table entries we have just identified. For the purpose of re-disassembly we will develop a sub-range which begins at the address contained in one symbol table entry and extends to the address contained in the next symbol table entry. We have already disassembled such a "suspect" program segment once. What we need now is a means to weigh what we'll ask our disassembler to take a second look at — re-disassemble. This is where the full compliment of instruction "types" become important. We will also provide two additional tools to use during this phase.

Our disassembler knows the start and end points of the requested disassembly. But what if that range represented only a portion of the complete program? A branch instruction with an object address outside this range would appear less valid than one whose object fell within this range. In the later, we would be inclined to consider that an instruction whereas in the former, we might see it as data. In an effort to enhance the accuracy of such evaluations, we will give the disassembler a "valid" range, which may or may not correspond to the disassembly range (the "VALID LO '/' HI?" prompt). Now the disassembler can apply this "valid" range to his evaluation of three-byte instructions (types #1, 2 = 5).

The final tool we will provide is the means to consider any suspect program segment in its entirety. We want to avoid classifying any program area as data or instructions on the basis of a single instruction. Any such decision should be cumulative. However, since each instruction must be considered individually we will offer an evaluation variable which can be dynamically altered depending upon the instruction type and the instruction's content. This evaluation variable will be subjected to factors which combine the effect of instruction type and content.

The factors, or weights, I've chosen can be found on line 30100 of the BASIC listing. They are actually applied at lines **5700-57900**. These factors are somewhat arbitrary and you readers certainly have my permission to alter them as you see fit — we call that "tuning". However, they seem to do the job for me. Here's how they work.

If a branch instruction (type #1) is encountered in this re-disassembly and, if the object address falls within the "valid" range, the disassembler will add a positive bias to the evaluation variable. If the object address is outside the "valid" range, a somewhat weaker negative bias is applied to the evaluation variable. The same approach is used with load instructions (type #2) but the effect on the evaluation variable is not as great. If a suspect instruction (type #6) is found, a strong negative bias is applied to the evaluation variable. Finally, if a non-instruction (remember, we're still disassembling sequentially at a location dependent upon the previous instruction's length) is encountered, type #3, the strongest negative bias is applied to the evaluation variable.

Once we complete this re-disassembly, if we find that the evaluation variable yields a positive result we can flag that symbol table entry as pointing to program logic. In reality, all symbol table entries are so flagged upon entry — innocent until proven guilty, as it were. If our evaluation variable remained zero, it means we don't have enough information to make a definite determination. We'll flag that entry as "unknown" and later, through convention, treat the program segment as instructions. However, if the evaluation variable is negative (a likely result if a non-instruction was encountered, a probable result if any "bad" branch or load instructions were found), we'll flag that symbol table entry as data. We should also ask our disassembler to find his second wind because there's more work to do with any such program segment (remember re-re-disassembly?).

There are a couple of reasons for taking what amounts to a third look at any "confirmed" data area. First, a single byte of data may have been interpreted as a multi-byte instruction during pass one. In such a case, we may run the risk of losing the beginning of an otherwise valid instruction through the interpretation of data bytes 2-3 as an address or value. This very situation was clearly illustrated in the earlier REMark disassembler at address 000033.

The second reason for re-examining this data area lies in the way our symbol table was constructed. The next entry in the table (the entry containing the ending address of this sub-range) got there for a reason. If that reason was because of JMP instruction (type #5) and, if that instruction now generates a "valid" object address, then we owe our symbol table one more entry — one corresponding to the beginning of that instruction. Such an approach allows us to properly evaluate and label the JMP instruction we find at address 000050 following the data at

address 000043. Our only risk in "forcing" entries in this way is a few extraneous labels during the final pass, with no harm done. I prefer that to too few labels.

With the evaluation phase we find the last maintainence being applied to our symbol table. We won't be adding any more entries. However, this entire process will be repeated with each non-branch table entry throughout the range of disassembly.

SYMBOL TABLE LABEL ASSIGNMENT

The time has come (finally?) to transform our lowly address table into a true symbol table. The entries are now flagged as program logic, unknown and data. These flags will control the disassembly process (how memory is looked at) during the final pass. But what about us, the user, and the effect symbolic label content has on readability? Wouldn't it be nice if the labels we develop also reflected the distinction of program logic, etc.? Well, why not?

Let's call program logic entries "RTN" (for routine), un known segments "UNK" and data areas "DAT". We'll call all external labels "EXT" and we will append to each label an indication of where it resides within the table. Thus, our first few entries might appear as "EXT.1", "RTN.2", "UNK.3" and "DAT.4". In this way, using the CTL-B and CTL-C provisions, we could return to command mode during symbol table review and issue the following immediate command:

```
S$(2)=LEFT$(S$(2),7)+"ANYVAL"
```

Now we have replaced "RTN.2" with "ANYVAL" while retaining the evaluation flag and address. Thereafter, the dis assembler would associate "ANYVAL" with value in the symbol table whenever it was used during the final pass. Thus we have a simple, effective means for user designated labels.

This technique can be used over a period of time, as program segment functions are identified by you, to make an extremely readable disassembly listing. If at any time you wished to terminate a final pass listing, and resume at the start of the final pass later, the following immediate mode commands would accomplish it: —

```
UNLOCK
```

```
1 CNTRL 0,65000: GOTO 34000
```

```
FDUMP "any name"
```

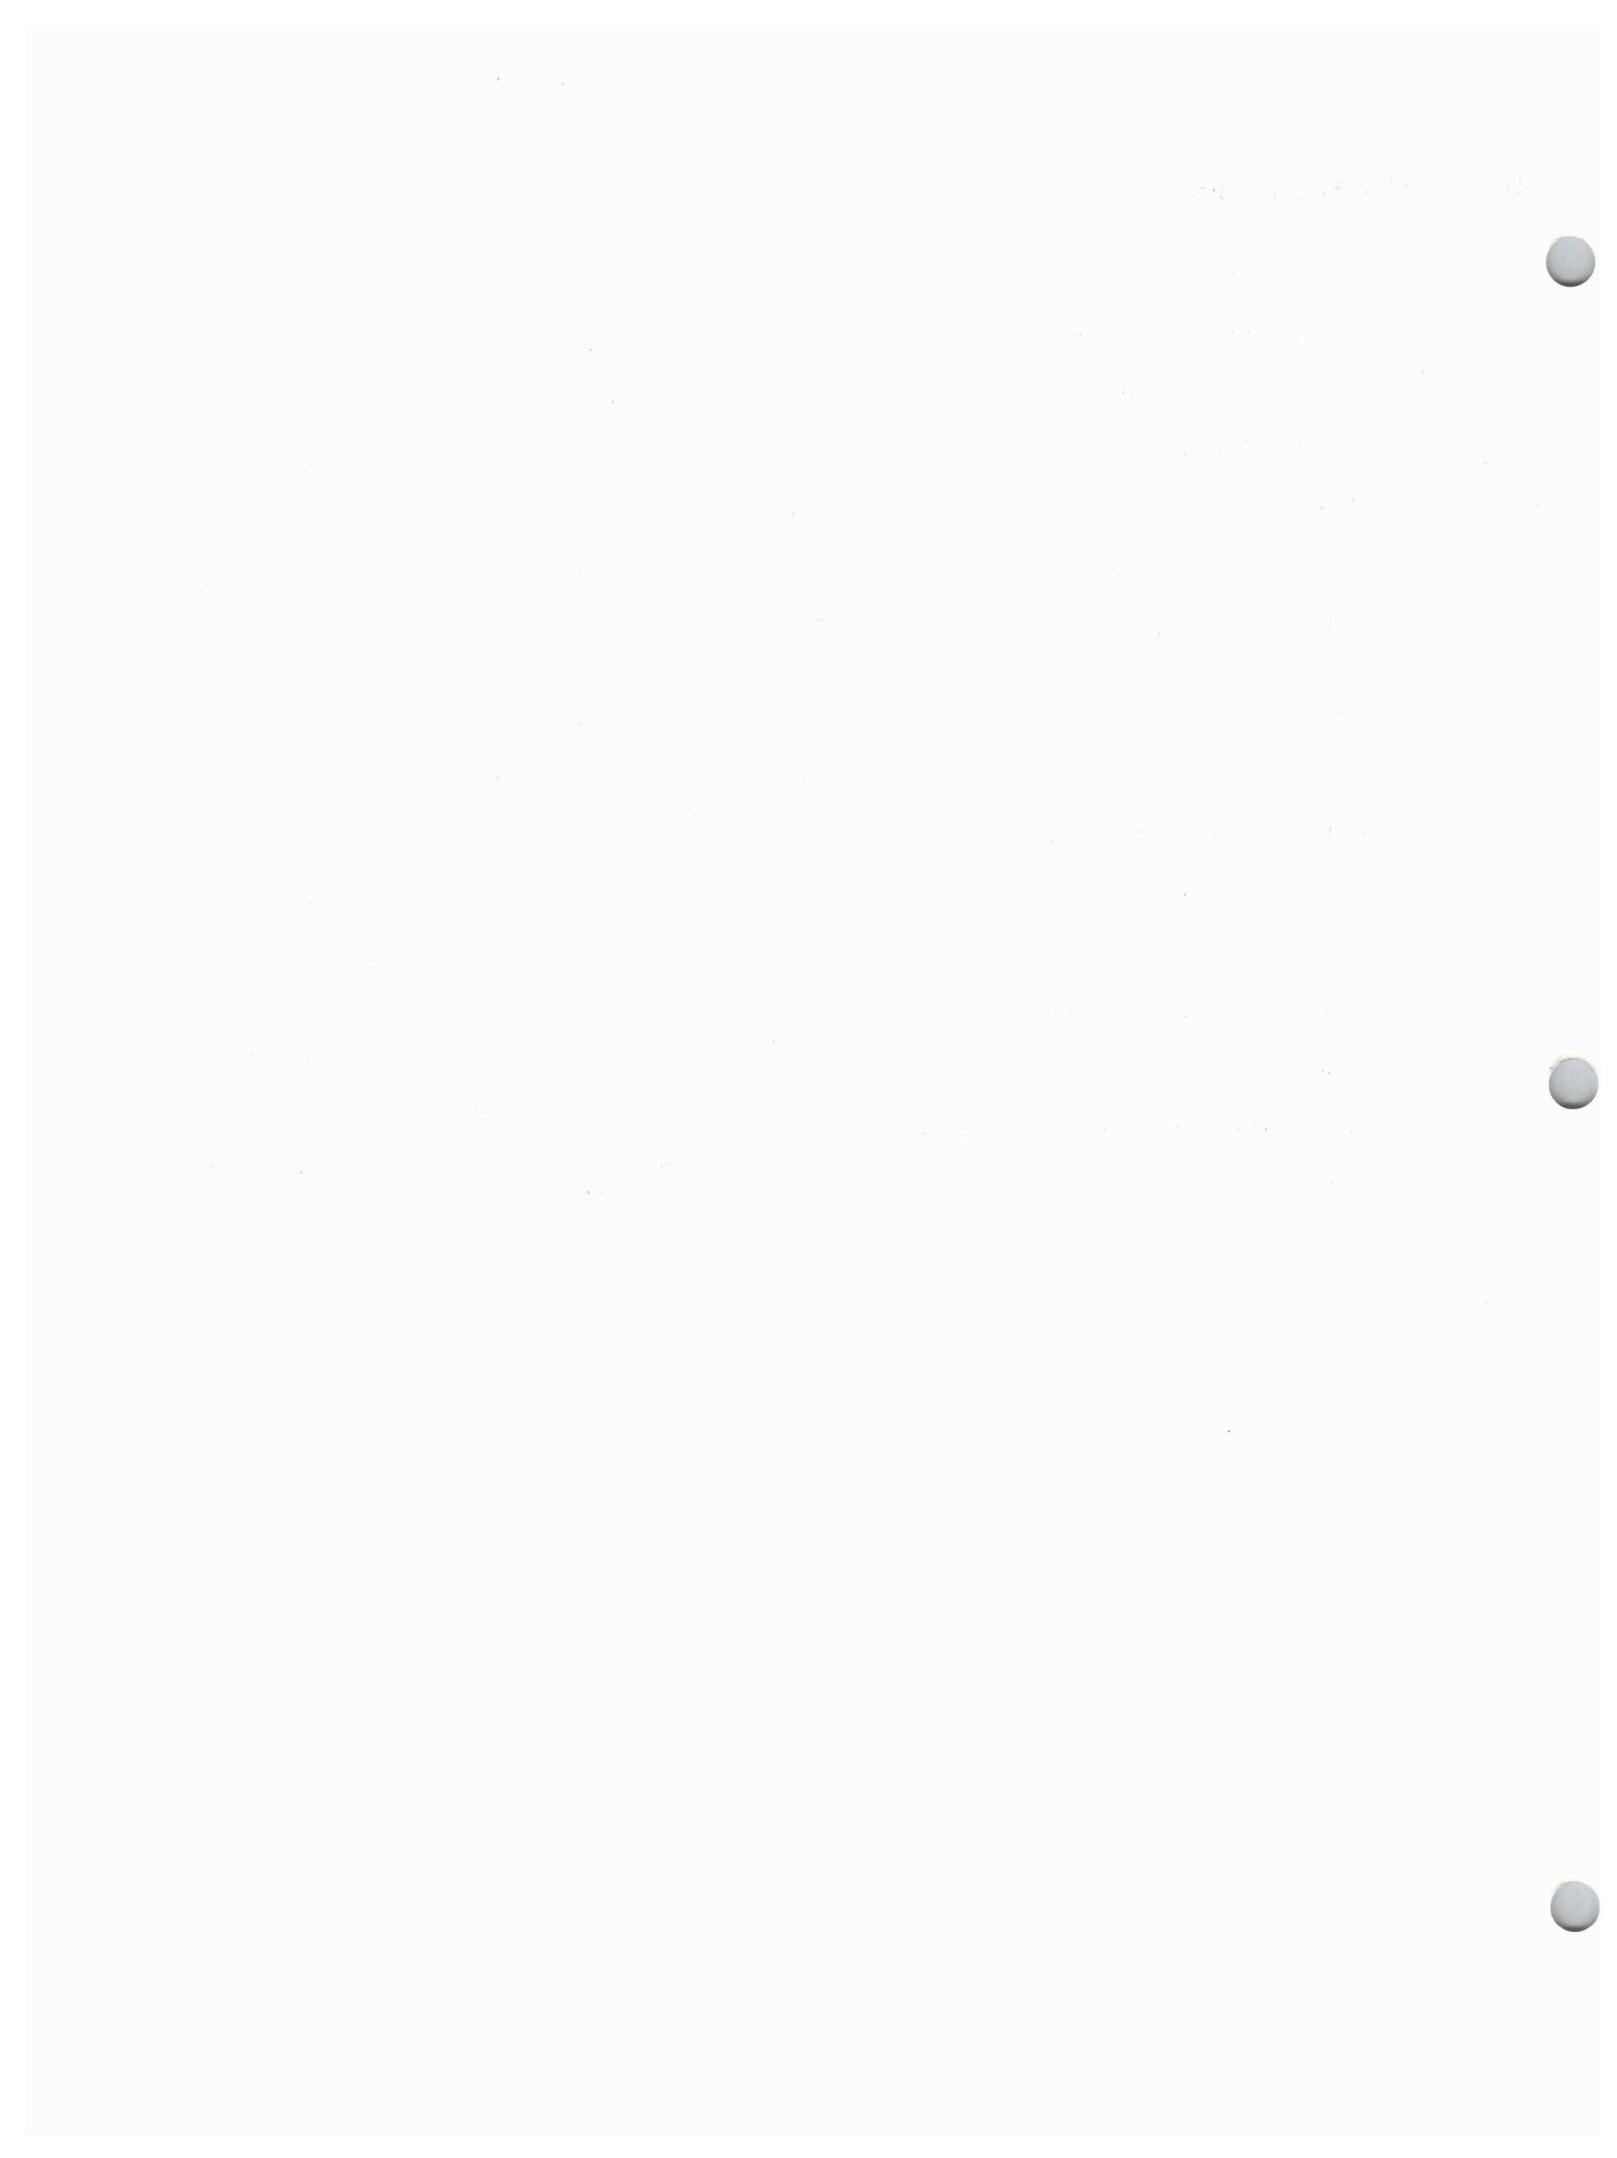

THE FINAL PASS

With labels assigned we can now begin our final pass, producing a symbolic assembly listing for our disassembly. Actually, this pass is not unlike the very first pass except we will be printing what we find as we PEEK() at various memory locations. Additionally, we'll use labels instead of octal values for three- byte instruction operands and we'll sometimes preface a line with a label — when that label's address matches our current memory location. Of course, if at that point the symbol table indicates we've reached a data area. We will force the "DB" (define byte) interpretation on what we find.

There you have it, symbolic (intelligent) disassembly. Simple, wasn't it?

PROGRAM VARIABLES

A	utility address, generally = P	P\$	utility offset octal address, generally user input
A\$	utility address in offset octal, generally = P		
C\$	mode identifier control byte/CTL-B enable	Q\$	utility octal value, from T\$(I)
E	disassembly end	Q1\$	symbolic two-byte instruction operand
E\$	disassembly end, offset octal	Q2\$	multi-byte instr's byte 2 octal value, from T\$(I)
F\$	absolute flag/CTL-B enable	Q3\$	multi- Q3\$ multi-byte instr's byte 3 octal value, from T\$(I)
I,I1	utility array reference indicies	S	disassembly start
I2,I3	symbolic re-disassembly symbol table reference indicies	S\$	disassembly start, offset octal
I\$	utility string	S\$(I)	symbol table
L	instruction length, from T\$(I)	T,T\$	instruction type, from T\$(I)
L\$	symbolic line prefix label	T1	symbolic evaluation variable
L1\$	symbolic instruction operand label	T(I)	symbolic symbol table type?references decode array
L9\$	symbolic end statement start label	T\$(I)	primary disassembler driving table
N\$	symbolic intregrity violation message	WO-W2	symbolic evaluation weights
O\$	instruction mnemonic op code, from T\$(I)	S1,S1\$ E1,E1\$	symbolic sub-range re-disassembly start/end addresses
P	current memory pointer

PROGRAM NAME: RENUMBER - IGNATIUS

TITLE 'EXTENDED B.H. BASIC RENUMBER OPTION VER. 1.0'
STL 'INSTRUCTIONS & DESCRIPTION'
**** EXTENDED B.H. BASIC RENUMBER OPTION
** WRITTEN BY MARK J. IGNATIUS
* LAKEWOOD, OHIO
* AUGUST 1978
*
* -INSTRUCTIONS AND DESCRIPTION-
* -MAKE COPIES FOR READY REFERENCE-
* -SEE PAGE 3 FOR ASSEMBLY INSTRUCTIONS-
*
* VER. 1.0
*
** THIS PROGRAM, WHEN RUN ALONG WITH EXTENDED
* B.H. BASIC, WILL ALLOW THE USER TO
* RENUMBER HIS PROGRAM STARTING WITH ANY LINE
* NUMBER AND IN ANY INCREMENT. THIS INCLUDES
* LINE NUMBER REFERENCES WITHIN THE TEXT.
*
** THIS PROGRAM RESIDES IN HIGH MEMORY AND IS
* SELF-CONFIGURING (IT WILL CONFIGURE HIGH
* MEMORY AUTOMATICALLY).
*
* THIS PROGRAM 'MUST' RESIDE IN HIGH MEMORY.
* DO NOT RUN A VERSION OF THIS PROGRAM CONFIGURED
* FOR LESS MEMORY THAN IN YOUR SYSTEM. IMPROPER
* OPERATION WILL RESULT.
*
* THIS PROGRAM CAN BE LOADED AFTER BASIC HAS
* BEEN UP & RUNNING. THERE IS NO NEED TO
* RELOAD BASIC.
* THIS PROGRAM MUST BE STARTED BY PUSHING GO
* AFTER LOADING.
*
* *** CAUTION ***
* LOADING THIS PROGRAM SCRATCHES USER PROGRAM.
* SAVE BASIC PROGRAM BEFORE LOADING.
*
*** SYNTAX:
*
* RENUMBER START AT LINE 10, INCREMENT OF 10

<H><U><G> <S><0><F><T><W><A><R><E> <V><0><L> II

PROGRAM NAME: RENUMBER - IGNATIUS < CONT'D >

```
*      RENUMBER X      START AT LINE X, INCREMENT OF 10
*      RENUMBER X,Y    START AT LINE X, INCREMENT OF Y
*
**   THIS COMMAND IS ENTERED IN THE COMMAND MODE
*   AS ANY OTHER COMMAND (EG. BUILD, LIST, RUN,
*   ETC.), WITH COMMAND COMPLETION.
*
**   **** SPECIAL NOTE ****
*   THIS PROGRAM REMOVES THE 'CONTINUE' COMMAND.
*   IT WILL NO LONGER BE VALID. TO SIMULATE
*   CONTINUE, USE THE 'STEP' COMMAND.
*
*      EJECT
***  -ERROR REPORTING-
*
*      WHEN THE COMMAND IS ENTERED AND THE CARRIAGE
*      RETURN HIT, THE COMMAND IS CHECKED FOR
*      VALID EXPRESSIONS. IF EITHER EXPRESSION
*      EVALUATES TO 0 OR 65535, OR THE RENUMBERING
*      CAUSES AN OVERFLOW OVER 65535, AN ERROR
*      MESSAGE IS GENERATED. THIS IS DONE PRIOR
*      TO THE ACTUAL RENUMBERING PROCESS SO NEW
*      VALUES MAY BE ENTERED.
*
*      ONCE THE RENUMBERING PROCESS BEGINS
*      (THE MESSAGE 'STANDBY' IS OUTPUT TO THE
*      CONSOLE), INTERRUPTS FROM THE CONSOLE ARE
*      DISABLED.
*
**   **** SPECIAL NOTE ****
*   IF THE PROGRAM IS INTERRUPTED (STOPPED) DURING
*   THE RENUMBERING PROCESS, THE USER PROGRAM WILL
*   BE DESTROYED AND WILL NOT FUNCTION CORRECTLY.
*   IF THE PROGRAM MUST BE STOPPED, RETURN TO THE
*   MONITOR AND DO A 'COLD' START AT 040.100.
*   THIS WILL OF COURSE SCRATCH THE USER PROGRAM,
*   BUT WILL NOT AFFECT BASIC OR THE RENUMBER
*   OPTION.
*
**   DURING THE RENUMBERING PROCESS, IF AN ERROR
*   IS FOUND, SUCH AS A MISSING LINE NUMBER
```

<H><U><G> <S><O><F><T><W><A><R><E> <U><O><L> II

PROGRAM NAME: RENUMBER - IGNATIUS < CONT'D >

```
*      (EG. GOTO 1000, WHERE LINE 1000 DOES NOT
*      EXIST), AN ERROR MESSAGE IS DISPLAYED
*      ON THE CONSOLE IN THE FORMAT:
*          ERR - LN# 500
*      THIS MEANS THAT LINE 500 WAS FOUND TO
*      HAVE AN ERROR IN IT. THE LINE NUMBER 500
*      IS THE LINE NUMBER OF THE PROGRAM 'BEFORE'
*      IT WAS RENUMBERED. ONLY THAT PART OF THE
*      LINE FOUND TO BE IN ERROR IS IGNORED.
*      THE REST OF THE LINE WILL BE FIXED.
*      THE SAME LINE NUMBER MAY BE LISTED MORE
*      THAN ONCE, AND ALL LINES WITH ERRORS
*      WILL BE LISTED.
*
**      IF, WHEN WORKING WITH A LARGE PROGRAM,
*      A LINE IS CHANGED TO CONTAIN MORE
*      CHARACTERS SO THAT A MEMORY OVERFLOW
*      WOULD RESULT, THE WHOLE LINE WILL BE IGNORED
*      AND AN ERROR MESSAGE WILL BE GENERATED
*      IN THE FORMAT EXPLAINED ABOVE.
*      ALSO, ANY CHANGE THAT WOULD CAUSE THE LINE
*      TO EXCEED 99 CHAR'S IS IGNORED AND AN ERROR
*      IS FLAGGED(AS ABOVE). SOME LINES MAY EXCEED
*      80 CHAR'S (81-99) AND NOT BE FLAGGED AS
*      ERRORS. THESE LINES ARE OK AND WILL FUNCTION
*      CORRECTLY.
*
      STL      'ASSEMBLY INSTRUCTIONS'
      EJECT
***** *****
*
***** ASSEMBLY INSTRUCTIONS
*
**      ALL THAT IS NECESSARY TO ASSEMBLE THIS
*      PROGRAM IS TO EQUATE TWO LABELS.
*      +++ NO OTHER UNDERSTANDING OF THIS
*      +++ PROGRAM IS NECESSARY.
*
**      -FIRST LABEL-
*      THE FOLLOWING LABEL ($MLMIT) IS TO BE SET TO
*      THE HIGEST MEMORY ADDRESS IN YOUR SYSTEM.
```

<H><U><G> <S><O><F><T><W><A><R><E> <V><O><L> II

PROGRAM NAME: RENUMBER - IGNATIUS < CONT'D >

* EXAMPLES:
* IF YOU HAVE 24K, SET EQU TO 177377A
* IF YOU HAVE 16K, SET EQU TO 137377A
*
* -HERE'S THE LABEL-

\$MLMIT EQU 137377A FOR 16K OF MEMORY

* THE PROGRAM WILL LOCATE ITSELF AND
* CONFIGURE HIGH MEMORY BASED ON THE
* ABOVE LABEL. THIS PROGRAM WILL START
* APPROXIMATELY 1K BELOW THE ABOVE LABEL.
* (ACTUAL PROGRAM IS 792 BYTES IN LENGTH)
*

** -SECOND LABEL-
* THE FOLLOWING LABEL (\$VERS) WILL DIRECT
* THE ASSEMBLER TO ASSEMBLE FOR THE VERSION
* OF EXTD. B.H. BASIC DESIRED.

* FOR VERSION 10.01.01 SET EQU TO 0
* FOR VERSION 10.02.01 SET EQU TO 1
*

* -HERE'S THE LABEL-

\$VERS EQU 0 FOR 10.01.01

*** AFTER THE ABOVE TWO LABELS HAVE BEEN
* CHANGED, THE PROGRAM SHOULD BE SAVED
* THEN ASSEMBLED.

*** ** NOTE **
* THIS PROGRAM IS SET UP SO THAT ALL DATA IS
* LISTED ON THE LIST DEVICE WHETHER ASSEMBLED
* OR NOT. DATA NOT ASSEMBLED WILL NOT HAVE DATA
* ON THE LEFT SIDE OF THE LISTING.

*
* STL 'EQUIVALENCES AND SETUP'

*** TITLE 'COMMAND COMPLETION SUPPRESSING CONSOLE DRIVER'
*** COMMAND COMPLETION SUPPRESSING CONSOLE DRIVER

* * BY MICHAEL WILLIAM MORGAN, AUGUST 1978.

*
*

*** THIS CONSOLE DRIVER WILL SUPPRESS COMMAND
* COMPLETION BY ANY PROGRAM WHICH USES THE H8
* CONSOLE DRIVER. THE PACKAGE PHYSICALLY
* REPLACES THE H8 CONSOLE DRIVER IN MEMORY,
* REQUIRING NO ADDITIONAL MEMORY, AND IS
* COMPATIBLE WITH ANY PROGRAM WHICH USES THE
* H8 CONSOLE DRIVER IN A NORMAL MANNER.

*
*

*** MUCH OF THIS DRIVER IS A COPY OR REVISION OF
* THE H8 CONSOLE DRIVER, WHICH IS COPYRIGHTED
* BY HEATH COMPANY, BENTON HARBOR, MI.

*
*

CONSTANTS

* * MACHINE INSTRUCTIONS:

MI.MVIA EQU 0760 MVI A.
MI.SUI EQU 3260 SUI.
MI.JMP EQU 3030 JMP.
